February 2009

Abstract

The recommended TAC output from the South African hake OMP-2006 for 2009 is 118 578 t. If the west coast survey abundance estimates for 2008 were omitted, this output would change to 123 768 t; if such estimates for both 2007 and 2008 were omitted, the output would become 117 450 t.

The 2009 TAC recommendation for the South African hake resource is computed in terms of the 2006 OMP (Rademeyer and Glazer, 2007) as follows:

\[ C_{y}^{opp} = C_{y-1}^{opp} \left[ 1 + \lambda_y \left( S_y^{opp} - \text{target}^{opp} \right) \right] \tag{1} \]

The computations input a TAC of 130 500 thousand tons for 2008. As specified in the OMP, this is disaggregated by species assuming the 2007 species-split of the catches, i.e. 80.98% (105 672 t) \( M. \) paradoxus and 19.02% (24 826 t) \( M. \) capensis to provide the \( C_{y}^{*opp} \) values for equation (1).

The GLM-standardised CPUE series (Glazer, 2008) and survey biomass abundance estimates (Leslie, 2008) used as inputs to the OMP are shown in Table 1 and the resulting trends in Fig. 1. Note that the results from surveys carried out with the Africana with new gear have been rescaled to take the calibration factor into account (this involves dividing new gear estimates by 0.95 for \( M. \) paradoxus and 0.80 for \( M. \) capensis), as specified in the OMP (Rademeyer and Glazer, 2007); the ‘true’ estimates are shown in parenthesis in Table 1.
The recent annual trend, $s_y$, computed from a specified weighted average of the CPUE and survey slopes (0.5 for CPUE and 0.25 for each survey), is -0.96% for $M. \ paradoxus$ and -13.44% for $M. \ capensis$.

From equation 4 ($\lambda_0 = \left\{ \begin{array}{ll} 0.06(y - 2006) + 0.5 & \text{if } s_y > 0 \\ -0.09(y - 2006) + 2.0 & \text{if } s_y \leq 0 \end{array} \right.$) of Rademeyer and Glazer (2007):

$$\lambda_{2009} = \left\{ \begin{array}{ll} 0.68 & \text{if } s_y > 0 \\ 1.73 & \text{if } s_y \leq 0 \end{array} \right.$$  

Thus the $M. \ paradoxus$ contribution to the TAC is:

$$C^\text{para}_{2009} = 105672\{1 + 1.73(-0.96\% - 2.4\%)\} = 99526\text{t}$$

and the $M. \ capensis$ contribution:

$$C^\text{cap}_{2009} = 24826\{1 + 1.73(-13.44\% - 0\%)\} = 19052\text{t}$$

The total 2009 TAC output from the OMP is therefore 118 578 t. This is 9.14% less than the 2008 TAC of 130 500 t, and so is not impacted by the OMP constraint that TACs not change by more than 10% per year.

If data from the 2008 west coast survey are omitted, the TAC output would be 123 768 t; if data for both the 2007 and 2008 west coast surveys are omitted, the TAC output would be 117 450 t (the 10% minimum TAC decrease constraint having come into play). Fig. 1 also includes the fitted trends under these two alternative sets of choices.

**References**

Table 1: GLM-standardised CPUE series and west coast summer and south coast autumn survey abundance estimates used as input in the 2009 TAC computation. Note that the abundance estimates in bold incorporate the calibration factors agreed for OMP application as they are for surveys in which the new gear was used on the *Africana*. The values in parentheses are the actual estimates obtained from the surveys.
